**"Genetic  
Evidence of  
Evolution:  
One Step  
Forward,  
Two Steps Back"**

**Nazareth Chapel, 3003 North Snelling, University of Northwestern - St. Paul**

Experimental evolution (observed changes over thousands of generations and trillions of organisms) was expected to show evolution of new genes. Instead, it shows: 1) loss of gene function to overcome a selective pressure, or 2) simple rearrangements of existing genetic structures, not new genes. The scope of evolutionary opportunity in these experiments is similar that of humans evolving from chimpanzees, but humans have hundreds of new genes compared to chimps. The results cast serious doubt on macroevolution.
